Analysis for Typhoon Bavi (WP0926) on July 9, 2026, at 15:00 UTC.

【Core Parameters】

- Maximum Wind Speed (VMAX): 99 knots (kt)
- Minimum Central Pressure (MSLP): 950.9 hectopascals (hPa)
- Radius of Maximum Winds (RMW): 18 nautical miles (nmi)
- Storm Center: Located near 19.5°N, 128.5°E

【Wind Radii by Quadrant (in nautical miles)】

The table at the bottom left details the extent of the 34-knot, 50-knot, and 64-knot wind thresholds across the Northeast (NE), Southeast (SE), Southwest (SW), and Northwest (NW) quadrants:

- 34-knot Wind Radius (R34): All direction 260-275
- 50-knot Wind Radius (R50): **NE 235** / SE 140 / SW 175 / NW 175
- 64-knot Wind Radius (R64): **NE 145** / SE 80 / SW 100 / NW 105

【Atypical Features】

- **Asymmetry structure.**

After July 10, 2026, at 15:00 UTC, Typhoon Bavi (09W) entered a stage of rapid asymmetric weakening and structural collapse.

【Comparison】

- VMAX: 99 → 81 kts.
- Minimum Central Pressure (MSLP): 950.9 hPa → 961.5 hPa
- Center Position: Moved northwestward from (19.5°N, 128.5°E) to approximately (23.2°N, 125.6°E).
- RMW: Remained at 18 nmi.

【Shrinking Wind Radii】

As the typhoon weakened noticeably:

- 64-knot Wind Radius (R64) quadrants:
 - Northeast (NE): 145 → 95 (shrank)
 - Southeast (SE): 80 → 20 (severe shrinkage; strong winds in the SE quadrant almost vanished)
 - Southwest (SW): 100 → 90
 - Northwest (NW): 105 → 95
- R50 quadrants: Shrank across all quadrants, with the Southeast quadrant showing the most severe reduction (140 → 120).

【Visual Features】

- Increased Asymmetry
- Upper-Level Dry Air Impact

WP0926

BAVI 2026 10 Jul 15UTC
